Duplicate keys

Often, purpose of sort is to bring items with equal keys together.

- Sort population by age.
- Remove duplicates from mailing list.
- Sort job applicants by college attended.

Typical characteristics of such applications.

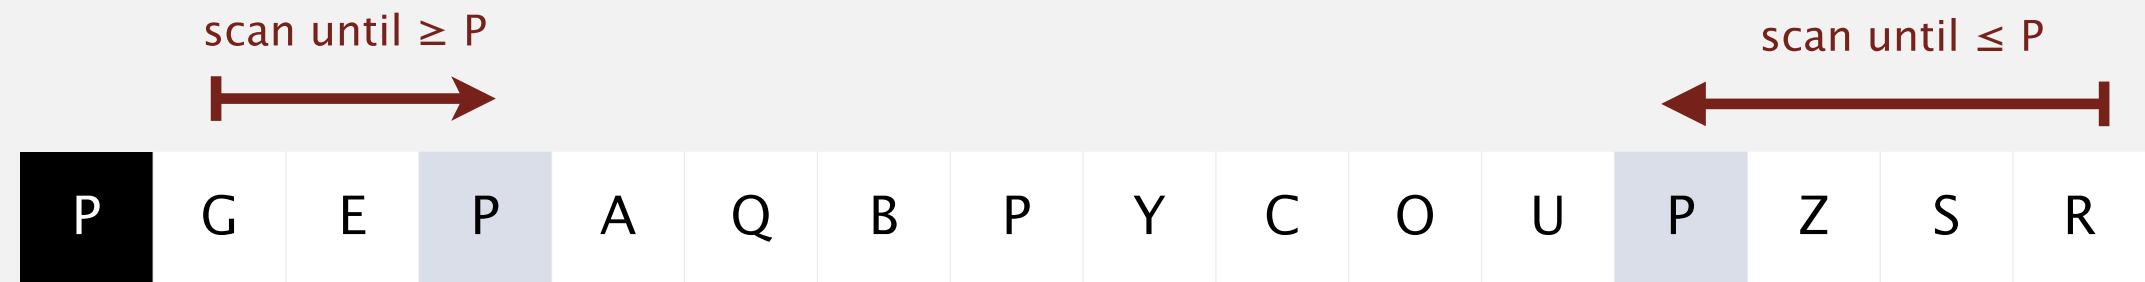

- Huge array.
- Small number of key values.

Duplicate keys: stop on equal keys

Our partitioning subroutine stops both scans on equal keys.

Q. Why not continue scans on equal keys?

Quicksort quiz 2

What is the result of partitioning the following array (skip over equal keys)?

A.

Duplicate keys: partitioning strategies

Bad. Don't stop scans on equal keys.

[$\sim \frac{1}{2} N^2$ compares when all keys equal]

B A A B A B B **B** C C C

A A A A A A A A A A **A**

Good. Stop scans on equal keys.

[$\sim N \lg N$ compares when all keys equal]

B A A B A **B** C C B C B

A A A A A **A** A A A A A

Better. Put all equal keys in place. How?

[$\sim N$ compares when all keys equal]

A A A **B B B B B** C C C

A A A A A A A A A A A

DUTCH NATIONAL FLAG PROBLEM

Problem. [Edsger Dijkstra] Given an array of N buckets, each containing a red, white, or blue pebble, sort them by color.

input

sorted

Operations allowed.

- $swap(i, j)$: swap the pebble in bucket i with the pebble in bucket j .
- $color(i)$: color of pebble in bucket i .

Requirements.

- Exactly N calls to $color()$.
- At most N calls to $swap()$.
- Constant extra space.

3-way partitioning

Goal. Partition array into **three** parts so that:

- Entries between lt and gt equal to the partition item.
- No larger entries to left of lt .
- No smaller entries to right of gt .

Dutch national flag problem. [Edsger Dijkstra]

- Conventional wisdom until mid 1990s: not worth doing.
- Now incorporated into C library `qsort()` and Java 6 system sort.

Dijkstra 3-way partitioning demo

- Let v be partitioning item $a[lo]$.
- Scan i from left to right.
 - ($a[i] < v$): exchange $a[lt]$ with $a[i]$; increment both lt and i
 - ($a[i] > v$): exchange $a[gt]$ with $a[i]$; decrement gt
 - ($a[i] == v$): increment i

invariant

3-way quicksort: Java implementation

```
private static void sort(Comparable[] a, int lo, int hi)
{
    if (hi <= lo) return;
    int lt = lo, gt = hi;
    Comparable v = a[lo];
    int i = lo;
    while (i <= gt)
    {
        int cmp = a[i].compareTo(v);
        if      (cmp < 0) exch(a, lt++, i++);
        else if (cmp > 0) exch(a, i, gt--);
        else          i++;
    }

    sort(a, lo, lt - 1);
    sort(a, gt + 1, hi);
}
```

Duplicate keys: lower bound

Sorting lower bound. If there are n distinct keys and the i^{th} one occurs x_i times, any compare-based sorting algorithm must use at least

$$\lg \left(\frac{N!}{x_1! x_2! \cdots x_n!} \right) \sim - \sum_{i=1}^n x_i \lg \frac{x_i}{N}$$

$N \lg N$ when all distinct;
linear when only a constant number of distinct keys

compares in the worst case.

Proposition. [Sedgewick-Bentley 1997]

Quicksort with 3-way partitioning is **entropy-optimal**.

Pf. [beyond scope of course]

Bottom line. Quicksort with 3-way partitioning reduces running time from linearithmic to linear in broad class of applications.

proportional to lower bound
